Chapter 1

Module 1: Chapter 5 - Electric Charges and Fields

From Newton's Second Laws of Mechanics:

$$F = ma \quad (1.1)$$

A force can be recognized by the effect it has on an object. When studying gravitation, we examined the force of gravity that acts on all objects with mass. Similarly, the electric force acts on all objects with a property called charge. While gravity is an attractive force, the electric force can be either attractive or repulsive.

1.1 Section 5.1 Electric Charge

The ancient Greek philosopher Thales of Miletus (624-546 BCE) recorded that when amber was vigorously rubbed with a piece of fur, it created a force that attracted them to each other. They also attracted other non-metallic objects even when not touched.

Figure 1.1: Materials rubbed together

The English physicist William Gilbert (1544-1603) also studied attractive forces. He worked with a variety of substances. His findings included:

- Metals never exhibited this force, whereas minerals did
- Two "electrified" amber rods would repel each other.

This suggested that there were two types of electric properties: attractive and repulsive. This property came to be known as Electric Charge. The force is repulsive between the same type of charge and attractive between the charges are of opposite types. Named after French physicist Charles Augustine de Coulomb (1736-1806), the unit of electric charge is the coulomb (C).

The American statesman and scientist Benjamin Franklin found that he could concentrate charge in Leyden jar ¹ (a glass jar with two metal sheets one on the inside and one on the outside (essentially what we now call a capacitor). Franklin pointed out that the behavior could be explained by one type of charge remaining motionless and the other charge flowing from one piece of foil to the other. He had no way of determining which type of charge was moving, and unfortunately he guessed wrong: it was since learned that the charges that flow are the ones that Franklin named "negative" and the "positive" charges remain motionless.

Figure 1.2: Leyden Jar

Observations about the Electric Force:

¹Its invention was a discovery made independently by German cleric Ewald Georg von Kleist on 11 October 1745 and by Dutch scientist Pieter van Musschenbroek of Leiden (Leyden), Netherlands in 1745–1746. The invention was named after the city.

- The force acts without physical contact between objects
- The force is attractive or repulsive
- Not all objects are affected by this force
- The magnitude of the force decreases rapidly with distance between objects

Properties of Electric Charge

- Charge is quantized - The smallest amount of charge an object can have is $e = 1.602 * 10^{-19}C$. The charge on any object must be an integer multiple of e .
- The magnitude of a charge is independent of the type. The smallest positive charge is $1.602 * 10^{-19}C$ and the smallest negative charge is $-1.602 * 10^{-19}C$; these values are exactly equal in magnitude.
- Charge is conserved. Charge can not be created or destroyed. It can only be transferred. The net charge of the universe is constant.
- Charge is conserved in a closed system. Total charge in a closed system remains constant.

These last two items are referred to as the Law of Conservation of Charge.

The Sources of Charge: The Structure of the Atom

Atomic structure terminology

- Electron
- Proton
- Neutron
- Ion

This simplified model of a hydrogen atom shows a positively charged nucleus (consisting, in the case of hydrogen, of a single proton), surrounded by an electron “cloud.” The charge of the electron cloud is equal (and opposite in sign) to the charge of the nucleus, but the electron does not have a definite location in space; hence, its representation here is as a cloud. Normal macroscopic amounts of matter contain immense numbers of atoms and molecules, and, hence, even greater numbers of individual negative and positive charges.

Figure 1.3: Simplified model of a hydrogen atom

The nucleus of a carbon atom is composed of six protons and six neutrons. As in hydrogen, the surrounding six electrons do not have definite locations and so can be considered to be a sort of cloud surrounding the nucleus.

Figure 1.4: Carbon atom

1.2 Conductors, Insulators, and Charging by Induction

Conductors

Electrons surround the tiny nucleus in the form of a (comparatively) vast cloud of negative charge. However, this cloud does have a definite structure to it. If we consider an atom of copper, there is an outermost electron that is only loosely bound

to the atom's nucleus. It can be easily dislodged; it then moves to a neighboring atom. In a large mass of copper atoms (such as a copper wire or a sheet of copper), these vast numbers of outermost electrons (one per atom) wander from atom to atom, and are the electrons that do the moving when electricity flows. These wandering, or “free,” electrons are called conduction electrons, and copper is therefore an excellent conductor (of electric charge). All conducting elements have a similar arrangement of their electrons, with one or two conduction electrons. This includes most metals.

Insulators

Insulators, in contrast, are made from materials that lack conduction electrons; charge flows only with great difficulty, if at all. Even if excess charge is added to an insulating material, it cannot move, remaining indefinitely in place. This is why insulating materials exhibit the electrical attraction and repulsion forces described earlier, whereas conductors do not; any excess charge placed on a conductor would instantly flow away (due to mutual repulsion from existing charges), leaving no excess charge around to create forces. Charge cannot flow along or through an insulator, so its electric forces remain for long periods of time. (Charge will dissipate from an insulator, given enough time.) As it happens, amber, fur, and most semi-precious gems are insulators, as are materials like wood, glass, and plastic.

Charging by Induction

Induced polarization: A positively charged glass rod is brought near the left side of the conducting sphere, attracting negative charge and leaving the other side of the sphere positively charged. Although the sphere is overall still electrically neutral, it now has a charge distribution, so it can exert an electric force on other nearby charges. Furthermore, the distribution is such that it will be attracted to the glass rod.

Figure 1.5: Induced Polarization

Both positive and negative objects attract a neutral object by polarizing its molecules.

- A positive object brought near a neutral insulator polarizes its molecules. There is a slight shift in the distribution of the electrons orbiting the molecule, with unlike charges being brought nearer and like charges moved away. Since the electrostatic force decreases with distance, there is a net attraction.
- A negative object produces the opposite polarization, but again attracts the neutral object.
- The same effect occurs for a conductor; since the unlike charges are closer, there is a net attraction.

Figure 1.6: Attraction to neutral objects

Charging by induction.

- Two uncharged or neutral metal spheres are in contact with each other but insulated from the rest of the world.
- A positively charged glass rod is brought near the sphere on the left, attracting negative charge and leaving the other sphere positively charged.
- The spheres are separated before the rod is removed, thus separating negative and positive charges.
- The spheres retain net charges after the inducing rod is removed—without ever having been touched by a charged object.

Figure 1.7: Charge by Induction

Similarly using a ground connection

Figure 1.8: Charge by Induction with Ground Connection

1.3 Coulombs Law

Recall from Physics I the gravitational force equation

$$F_G = G \frac{m_1 m_2}{r^2} \quad (1.2)$$

Figure 1.9: Newtons Law Gravitation

For the electric force, let

- q_1, q_2 = the net electric charges of two objects
- \vec{r}_{12} = the vector displacement from q_1 to q_2 .

$$F \propto \frac{q_1 q_2}{r_{12}^2} \quad (1.3)$$

Figure 1.10: Electrostatic Force

Coulomb's Law: the electric force between two electrically charged particles is given by

$$\vec{F} = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r_{12}^2} \hat{r}_{12} \quad (1.4)$$

where \hat{r}_{12} is the unit vector from particle 1 to particle 2, and where ϵ_0 is the permittivity of free space

$$\epsilon_0 = 8.85 * 10^{-12} \frac{C^2}{N \cdot m^2} \quad (1.5)$$

Which leads to Coulomb's constant (k):

$$k = \frac{1}{4\pi\epsilon_0} = 8.99 * 10^9 \frac{N \cdot m^2}{C^2} \quad (1.6)$$

Example: Force on the Electron in a Hydrogen Atom

Proton has a positive charge of $+e$, and an electron has a negative charge of $-e$. In the "ground state" of the atom, the electron orbits the proton at a probably distance of $5.29 * 10^{-11}m$.

$$q_1 = +e = +1.602 * 10^{-19}C \quad (1.7)$$

$$q_2 = -e = -1.602 * 10^{-19}C \quad (1.8)$$

$$r = 5.29 * 10^{-11}m \quad (1.9)$$

The magnitude of the force

$$F = \frac{1}{4\pi\epsilon_0} \frac{|e|^2}{r^2} = 8.99 * 10^9 \frac{N \cdot m^2}{C^2} * \frac{(1.602 * 10^{-19}C)^2}{(5.29 * 10^{-11}m)^2} = 8.25 * 10^{-8}N \quad (1.10)$$

The force is thus expressed as

$$\vec{F} = (8.25 * 10^{-8}N)\hat{r} \quad (1.11)$$

Multiple Sources of Charge

As with the forces encountered in Physics I, the net electric force is the vector sum of the individual forces.

$$\vec{F}(r) = \frac{1}{4\pi\epsilon_0} Q \sum_{i=1}^N \frac{q_i}{r_i^2} \hat{r}_i \quad (1.12)$$

where Q represents the charge of a particle that experiences the force \vec{F} and is located at \vec{r} from the origin; q_i are the N source charges, and the vectors $\vec{r}_i = r_i \hat{r}_i$ are the displacements from the position of the i th charge to the position of Q . All of this is with the simplifying assumption that the source charges are all fixed in place somehow. This is referred to as the electrostatic force.

Figure 1.11: Multiple Source Charges

insert example 5.2

1.4 Electric Field

Next we define the Electric Field, which is independent of the test charge Q , and only depends on the configuration of the source charges.

$$\vec{F} = Q \cdot \vec{E} \quad (1.13)$$

where

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \sum_{i=1}^N \frac{q_i}{r_i^2} \hat{r}_i \quad (1.14)$$

expresses the Electric Field at position $P = P(x, y, z)$ of the N source charges.

This is analogous to the gravitational field \vec{g} of the Earth

Figure 1.12: Electric Field - Multiple Source Charges

$$\vec{g} = G \frac{M}{r^2} \hat{r} \quad (1.15)$$

which gives us $9.81 \frac{m}{s^2}$ near the Earth's surface.

The Electric Field is

- A vector field
- Obeys superposition
- By convention, the Electric Field points away from the positive charge.

1.5 Calculating Electric Field Charge Distributions

Definitions of charge density

- $\lambda \equiv$ charge per unit length (linear charge density) in $\frac{C}{m}$
- $\sigma \equiv$ charge per unit area (surface charge density) in $\frac{C}{m^2}$
- $\rho \equiv$ charge per unit volume (volume charge density) in $\frac{C}{m^3}$

Figure 1.13: Configuration of Charge

Given these densities, the differential charge (dq) becomes λdl , σdA , and ρdV , respectively.

For these distributions, the summation becomes an integral

- Point Charge

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \sum_{i=1}^N \frac{q_i}{r^2} \hat{r} \quad (1.16)$$

- Line Charge

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_{line} \left(\frac{\lambda dl}{r^2} \right) \hat{r} \quad (1.17)$$

- Surface Charge

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_{surface} \left(\frac{\sigma dA}{r^2} \right) \hat{r} \quad (1.18)$$

- Volume Charge

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_{volume} \left(\frac{\rho dV}{r^2} \right) \hat{r} \quad (1.19)$$

As $P = P(x, y, z)$, the integral is shorthand for three integrals (one in each direction)

$$\vec{E}_x(P) = \frac{1}{4\pi\epsilon_0} \int_{line} \left(\frac{\lambda dl}{r^2} \right)_x, \vec{E}_y(P) = \frac{1}{4\pi\epsilon_0} \int_{line} \left(\frac{\lambda dl}{r^2} \right)_y, \vec{E}_z(P) = \frac{1}{4\pi\epsilon_0} \int_{line} \left(\frac{\lambda dl}{r^2} \right)_z \quad (1.20)$$

Electric Field of a Line Segment

Figure 1.14: A uniformly charged segment of wire. The electric field at point P can be found by applying the superposition principle to symmetrically placed charge elements and integrating.

Start with

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_{line} \left(\frac{\lambda dl}{r^2} \right) \hat{r} \quad (1.21)$$

The symmetry of the arrangement implies the horizontal components cancel.

$$\vec{E}(P) = \vec{E}_1 + \vec{E}_2 = E_{1,x}\hat{i} + E_{1,z}\hat{k} + E_{2,x}(-\hat{i}) + E_{2,z}\hat{k} \quad (1.22)$$

Due to symmetry, $E_{1,x} = E_{2,x}$, and as their directions are opposite, they cancel. So,

$$\vec{E}(P) = E_{1,z}\hat{k} + E_{2,z}\hat{k} = E_1 \cos \theta \hat{k} + E_2 \cos \theta \hat{k} \quad (1.23)$$

As these components are also equal, substituting into Equation 1.21 yields:

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_0^{\frac{L}{2}} \left(\frac{2\lambda dx}{r^2} \cos \theta \right) \hat{k} \quad (1.24)$$

To calculate the integral, we note that

$$r = \sqrt{(x^2 + z^2)} \quad (1.25)$$

and

$$\cos \theta = \frac{z}{r} = \frac{z}{\sqrt{(x^2 + z^2)}} = \frac{z}{(x^2 + z^2)^{\frac{1}{2}}} \quad (1.26)$$

Substituting for $\cos \theta$:

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_0^{\frac{L}{2}} \left(\frac{2\lambda dx}{(x^2 + z^2)} \frac{z}{(x^2 + z^2)^{\frac{1}{2}}} \right) \hat{k} \quad (1.27)$$

$$\vec{E}(P) = \frac{1}{4\pi\epsilon_0} \int_0^{\frac{L}{2}} \left(\frac{2\lambda z}{(x^2 + z^2)^{\frac{3}{2}}} \right) dx \hat{k} \quad (1.28)$$

Integrating utilizing Trig Substitution (See Appendix A):

$$\vec{E}(P) = \frac{2\lambda z}{4\pi\epsilon_0} \left[\frac{x}{z^2 \sqrt{(x^2 + z^2)}} \right] \Big|_0^{\frac{L}{2}} \hat{k} \quad (1.29)$$

or

$$\vec{E}(z) = \frac{1}{4\pi\epsilon_0} \frac{\lambda L}{z \sqrt{(\frac{L}{4} + z^2)}} \hat{k} \quad (1.30)$$

For an infinite line: $L = \infty$

$$\vec{E}(z) = \frac{1}{4\pi\epsilon_0} \frac{2\lambda}{z} \hat{k} \quad (1.31)$$

noting that we lost the $\frac{1}{r^2}$ dependence

For a finite line of charge with $z \gg L$

$$\vec{E}(z) = \frac{1}{4\pi\epsilon_0} \frac{\lambda L}{z^2} \hat{k} \quad (1.32)$$

Recalling that $q = \lambda L$, then we get the expression of the field of a point charge.

1.6 Electric Field Lines

Electric Field Lines allow us to visualize the electric field in space

Figure 1.15: Vector field of dipole

Electric Field Line "Rules"

- Either begin at a positive charge or come in from infinity
- Either end at a negative charge or extend out to infinity
- The number of lines originating or terminating is proportional to the amount of charge.
- The density at any point in space is proportional to (and therefore is representative of) the magnitude of the field at that point in space

- The field lines never cross

Figure 1.16: Electric Field of a dipole

Figure 1.17: Field Line Density

Figure 1.18: Typical Diagrams

Chapter 2

Module 2: Chapter 6 - Gauss's Law

Four main topics:

- Electric Flux
- Gauss's Law
- Calculating Electric Field with Gauss's Law
- Electric Field inside Conductors

2.1 Electric Flux

Flux describes how much of something goes through a given area. More formally, flux is the dot-product of a vector field (in our case, the electric field) with an area.

Figure 2.1: Flux through a plane

Electric Flux

For uniform field \vec{E} and a flat surface:

$$\Phi = \vec{E} \cdot \vec{A} \quad (2.1)$$

$$\Phi = EA \cos \theta \quad (2.2)$$

Figure 2.2: Flux through a cube

- Source and termination of electric field lines are outside the cube
- There is no charge inside the cube
- All electric field lines that enter the cube exit it, so the net flux through the cube is zero.
- By convention: if field lines are leaving a closed surface then Φ is positive.
- For field lines entering a closed surface, Φ is negative.

For a non-flat surface, we can take small patches that approximate a flat surface

Figure 2.3: Surface divided into patches to find flux

Consider \vec{E}_i to be the electric field over the i^{th} patch (δA_i), then

$$\Phi_i = \vec{E}_i \cdot \delta \vec{A}_i \quad (2.3)$$

then

$$\Phi = \sum_{i=1}^N \Phi_i = \sum_{i=1}^N \vec{E}_i \cdot \delta \vec{A}_i \quad (2.4)$$

As the patch gets infinitesimally small,

$$\delta \vec{A} \rightarrow \hat{n} dA \quad (2.5)$$

and the \sum become an \int_s over the entire surface

For an Open Surface:

$$\Phi = \int_s \vec{E} \cdot \hat{n} dA = \int_s \vec{E} \cdot d\vec{A} \quad (2.6)$$

For an Closed Surface:

$$\Phi = \oint_s \vec{E} \cdot \hat{n} dA = \oint_s \vec{E} \cdot d\vec{A} \quad (2.7)$$

2.2 Gauss's Law

Let's calculate the electric flux through a sphere that surrounds a point charge q .

Recall at Point P

$$\vec{E}_P = \frac{1}{4\pi\epsilon_0} \frac{q}{r^2} \hat{r} \quad (2.8)$$

where \hat{r} is the radial unit vector charge at the center to Point P .

Figure 2.4: Closed sphere around point charge P

Applying the flux equation 2.7, where $\hat{n} = \hat{r}$ and $r = R$, for infinitesimal area dA :

$$d\Phi = \vec{E} \cdot \hat{n} dA = \frac{1}{4\pi\epsilon_0} \frac{q}{R^2} \hat{r} \cdot \hat{r} dA = \frac{1}{4\pi\epsilon_0} \frac{q}{R^2} dA \quad (2.9)$$

Integrating

$$\Phi = \frac{1}{4\pi\epsilon_0} \frac{q}{R^2} \oint_s dA = \frac{1}{4\pi\epsilon_0} \frac{q}{R^2} (4\pi R^2) = \frac{q}{\epsilon_0} \quad (2.10)$$

As r increases, there is a $\frac{1}{r^2}$ decrease in electric field counteracts the r^2 increase in the surface of the sphere and we find that $\Phi = \frac{q}{\epsilon_0}$ is independent of the size of the sphere.

Gauss's Law

$$\boxed{\Phi_{closed surface} = \frac{q_{enc}}{\epsilon_0}} \quad (2.11)$$

where q_{enc} is the net charge enclosed by the surface

2.3 Applying Gauss's Law

Charge Distribution with Spherical Symmetry

Charge distribution is considered spherically symmetric if the density of charge depends only on the distance from a point in space and not direction. A spherically symmetric charge distribution does not change if you rotate the sphere.

$$\rho(r, \theta, \phi) = \rho(r) \quad (2.12)$$

For spherically symmetric:

$$\vec{E}_P = E_P(r)\hat{r} \quad (2.13)$$

The magnitude of the electric field \vec{E} is the same everywhere on a spherical Gaussian surface concentric with the distribution. For a sphere of radius r :

$$\Phi = E_P 4\pi r^2 \quad (2.14)$$

From Gauss's Law

$$4\pi r^2 E = \frac{q_{enc}}{\epsilon_0} \quad (2.15)$$

Combining, the magnitude $E(r)$ is given by

$$E(r) = \frac{1}{4\pi\epsilon_0} \frac{q_{enc}}{r^2} \quad (2.16)$$

For a sphere of radius R

$$q_{enc} = \begin{cases} q_{tot}, & \text{if } r \geq R. \\ q_{(r < R)}, & \text{if } r < R. \end{cases} \quad (2.17)$$

Which leads to an Electric Field at point P (E_{out} for P outside the sphere, and E_{in} for P inside the sphere)

Figure 2.5: Outside and inside the sphere

$$E_{out} = \frac{1}{4\pi\epsilon_0} \frac{q_{tot}}{r^2} \quad (2.18)$$

$$E_{in} = \frac{1}{4\pi\epsilon_0} \frac{q_{(r < R)}}{r^2} \quad (2.19)$$

So, what is q_{enc} inside the sphere. Let's assume uniform distribution of charge ρ_o

$$q_{enc} = \int \rho_0 dV = \int_0^r \rho_0 4\pi r' dr' = \rho_0 \left(\frac{4}{3} \pi r^3 \right) \quad (2.20)$$

Therefore

$$E_{out} = \frac{1}{4\pi\epsilon_0} \frac{q_{tot}}{r^2}, \text{ with: } q_{tot} = \frac{4}{3} \pi R^3 \rho_0 \quad (2.21)$$

$$E_{in} = \frac{1}{4\pi\epsilon_0} \frac{q(r < R)}{r^2} = \frac{\rho_0 r}{3\epsilon_0}, \text{ since: } q(r < R) = \frac{4}{3}\pi r^3 \rho_0 \quad (2.22)$$

Figure 2.6: Electric Field of uniformly charged non-conducting sphere

Charge Distribution with Symmetric Cylinder

Charge distribution is considered cylindrical symmetric if the density of charge depends only on the distance r from the axis, and does not vary along or with direction of axis.

Consider an "infinitely¹ long" cylinder with cylindrical symmetric charge distribution.

$$\rho(r, \theta, z) = \rho(r) \quad (2.23)$$

$$\vec{E}_P = E_P(r) \hat{r} \quad (2.24)$$

¹In the real world, cylinders are not finite, but if the length $L \gg r$ then it can be approximated as infinitely long

Figure 2.7: Cylindrically symmetric of length L

The electric field is perpendicular to the sides and parallel to the end caps.

The flux through the cylinder part is

$$\int_s \vec{E} \cdot \hat{n} dA = E \int_s dA = E(2\pi r L) \quad (2.25)$$

and the flux through the caps is zero, because

$$\vec{E} \cdot \hat{n} = 0 \quad (2.26)$$

The total flux is then

$$\int_s \vec{E} \cdot \hat{n} dA = 2\pi r L E + 0 + 0 = 2\pi r L E \quad (2.27)$$

Using Gauss's law and taking λ_{enc} to be the charge per unit length

$$q_{enc} = \lambda_{enc} L \quad (2.28)$$

$$\Phi = 2\pi r L E = \frac{q_{enc}}{\epsilon_0} \quad (2.29)$$

The magnitude of \vec{E}

$$E(r) = \frac{\lambda_{enc}}{2\pi\epsilon_0} \frac{1}{r} \quad (2.30)$$

$$\lambda_{enc}L = \begin{cases} q_{tot}, & \text{if } r \geq R. \\ q_{(r < R)}, & \text{if } r < R. \end{cases} \quad (2.31)$$

What happens if it is a cylindrical shell vs a solid cylinder?

Consider surface charge density of σ .

Figure 2.8: Gaussian surface around a cylindrical shell

$$\lambda_{enc} = \frac{\sigma 2\pi R L}{L} = 2\pi R \sigma \quad (2.32)$$

For point P outside of the shell $r \geq R$:

$$\vec{E} = \frac{2\pi R \sigma}{2\pi\epsilon_0} \frac{1}{r} \hat{r} = \frac{R\sigma}{\epsilon_0} \frac{1}{r} \hat{r} \quad (2.33)$$

For point P inside of the shell $r < R$:

$$\lambda_{enc} = 0 \quad (2.34)$$

so

$$\vec{E} = 0 \quad (2.35)$$

Planar Symmetry

Figure 2.9: Thin Charged Sheet

Consider a large flat surface with uniform charge density. The charge density is the same at all points (x,y), so the electric field \vec{E} at point P only depends on the z-coordinate.

$$\vec{E} = E(z)\hat{z} \quad (2.36)$$

Note that $E(z) = E(-z)$ though the direction is opposite.

Let the electric field at point P be $E_P = E(z)$. If the charge is positive, the field lines point away from the sheet, so

$$\Phi = \oint_S \vec{E}_P \cdot \hat{n} dA = E_P A + E_P A + 0 + 0 + 0 + 0 = 2E_P A \quad (2.37)$$

The charge inside the gaussian box on the plane is

$$q_{enc} = \sigma A \quad (2.38)$$

Given Gauss's law ($\Phi = \frac{q_{enc}}{\epsilon_0}$) :

$$\frac{q_{enc}}{\epsilon_0} = \frac{\sigma A}{\epsilon_0} \quad (2.39)$$

$$E_P = \frac{\Phi}{2A} = \frac{\sigma}{2\epsilon_0} \quad (2.40)$$

$$\vec{E}_P = \frac{\sigma}{2\epsilon_0} \hat{n} \quad (2.41)$$

with $\hat{n} = +\hat{z}$ above the plane and $\hat{n} = -\hat{z}$ below the plane, and E_P doesn't depend on the distance above the plane for an infinite plane. Practically, this is a useful approximation for a finite plate near the center.

2.4 Conductors in Electrostatic Equilibrium

Moving from insulators to conductors. The electric field in conductors exerts a force on the free electrons (conduction electrons). As these electrons are not bound to an atom, they accelerate. However, moving charges are not static, so when electrostatic equilibrium is reached the charges are distributed in such a way that the electric field inside the conductor vanishes.

Electric Field inside a Conductor vanishes

Figure 2.10: Metallic Sphere in presence of point charge

The redistribution of charges is such that

$$\vec{E}_P = \vec{E}_q + \vec{E}_A + \vec{E}_B = \vec{0} \quad (2.42)$$

for induced charge $-\sigma_A$ and $+\sigma_B$

There is no net charge enclosed by a Gaussian surface that is solely within the volume of a conductor at equilibrium. This gives us $q_{enc} = 0$ and

The redistribution of charges is such that

$$\vec{E}_{net} = \vec{0} \text{ at points inside a conductor} \quad (2.43)$$

Charge on a conductor

A consequence of a conductor in static equilibrium is that excess charge will end up on the outer surface of the conductor regardless of its origin.

Figure 2.11: Gaussian surface just below conductor surface

Since $E = 0$ everywhere inside the conductor,

$$\oint_s \vec{E} \cdot \hat{n} dA = 0 \quad (2.44)$$

As the Gaussian surface lies infinitesimally below the actual surface, and there is no charge within the Gaussian surface, then all the excess charge must be on the surface.

Electric Field at the Surface of a Conductor

If the electric field had a component parallel to the surface of the conductor, then the charges would move, which violates the electrostatic equilibrium assumption. Therefore the field must be normal to the surface.

Just above the surface the magnitude of the electric field (E) and the surface charge density (σ) are related by

$$E = \frac{\sigma}{\epsilon_0} \quad (2.45)$$

Figure 2.12: Field over the surface of a conductor

Consider an infinitesimally small cylinder on the surface of a conductor with one face inside the conductor and one face outside. The height is δ and the cross section ΔA .

Given that ΔA is infinitesimally small, the total charge in the cylinder is $\sigma \Delta A$.

The field is perpendicular to the surface, and thus the flux

$$\Phi = E \Delta A = \frac{\sigma \Delta A}{\epsilon_0} \quad (2.46)$$

yielding that charge right above the surface being given by:

$$E = \frac{\sigma}{\epsilon_0} \quad (2.47)$$

Electric Field of a Conducting Plate

Figure 2.13: Conducting Plate

A conducting plate is similar to the thin conducting plate, however, with $E = 0$ inside the conductor,

$$\Phi = \oint_S \vec{E}_P \cdot \hat{n} dA = E_P A + 0 + 0 + 0 + 0 + 0 = E_P A \quad (2.48)$$

and thus

$$E = \frac{\sigma}{\epsilon_0} \quad (2.49)$$

Example: Parallel Plates

Now consider the electric field between two oppositely charged parallel plates.

If the surface charge density is $\sigma = 6.81 * 10^{-7} \frac{C}{m^2}$ and the distance between the plates is $l = 6.50mm$, what is the electric field?

Figure 2.14: Between Conducting Plates

$$E = \frac{\sigma}{\epsilon_0} = \frac{6.81 * 10^{-7} \frac{C}{m^2}}{8.85 * 10^{-12} \frac{C^2}{N \cdot m^2}} = 7.69 * 10^4 \frac{N}{C} \quad (2.50)$$

Chapter 3

Module 3: Chapter 7 - Electric Potential

3.1 Electric Potential Energy

Figure 3.1: Charge and Mass in Gravity analogy

A charge accelerated by an electric field is analogous to a mass going down a hill. Thus, when a free charge is accelerated by an electric field it is also given kinetic energy. This kinetic energy exactly equals the decrease in potential energy.

The electrostatic (or Coulomb) force is conservative. This means the work done on charge q is independent of the path taken.

Figure 3.2: Displacement of "test" charge Q

Consider fixed charge $+q$ located at the origin. Push test charge $+Q$ towards $+q$ in such a way that the applied force \vec{F} exactly balances out the electric force \vec{F}_e .

In mechanics, $W = \text{mass} * \text{displacement}$; similarly, for the electric field, the work done moving charge $+Q$ from P1 to P2 is found by

$$W_{12} = \int_{P_1}^{P_2} \vec{F} \cdot d\vec{l} \quad (3.1)$$

Because \vec{F} balances out \vec{F}_e :

$$\vec{F} = -\vec{F}_e = -k \frac{qQ}{r^2} \hat{r} \quad (3.2)$$

Recalling Coulomb's constant: $k = \frac{1}{4\pi\epsilon_0} = 8.99 * 10^9 \frac{N \cdot m^2}{C^2}$

Finally, let U denote Potential Energy in Joules ($J = N \cdot m$). Negative work mean gain in potential energy

$$\Delta U = -W \quad (3.3)$$

Because the electrostatic force is conservative, the work W is independent of the path taken. Consider

Figure 3.3: Work independent of path taken

The work on path P_1P_2 is equal to the work along path $P_1P_3P_4P_2$. And, in fact, the work on paths P_1P_3 and P_4P_2 are both zero as the $d\vec{r}$ is perpendicular to the electric field along these segments.

Example

How much work is required to assemble this charge configuration:

Figure 3.4: Work independent of path taken

1. Lower left: first bring this $2\mu C$ charge to the origin. This requires no work as there are no yet any other charges, and thus no electric field.
2. Lower right: bring $3\mu C$ charge to (x,y,z) coordinates (1 cm, 0, 0)

$$W_2 = k \frac{q_1 q_2}{r_{12}} = (9.0 \times 10^9 \frac{N \cdot m^2}{C^2}) \frac{(2 \times 10^{-6} C)(3 \times 10^{-6} C)}{1.0 \times 10^{-2} m} = 5.4 J \quad (3.4)$$

3. Upper right: $r_{23} = 1.0 cm$ and $r_{13} = \sqrt{2.0} cm$

$$W_3 = 15.9 J \quad (3.5)$$

4. Upper left: Similarly, $r_{14} = 1.0\text{cm}$, $r_{34} = 1.0\text{cm}$ and $r_{23} = \sqrt{2}\text{cm}$

$$W_4 = 36.5J \quad (3.6)$$

$$W_{total} = W_1 + W_2 + W_3 + W_4 = 0 + 5.4J + 15.9J + 36.5J = 57.8J \quad (3.7)$$

In general

$$W_{123\dots N} = \frac{1}{2}k \sum_i^N \sum_j^N \frac{q_i q_j}{r_{ij}} \text{ for } i \neq j \quad (3.8)$$

The $\frac{1}{2}$ accounts for each pairing being counted twice.

3.2 Electric Potential and Potential Difference

The electric field is independent of the test charge. Calculating W directly can be difficult as direction and magnitude of \vec{F} since $W = \vec{F} \cdot \vec{d}$ can be complex for multiple charges, odd shapes, and arbitrary paths. However, because we know $\vec{F} = q\vec{E}$ that the work and hence ΔU is proportional to the test charge q .

To have a physical quantity independent of the test charge, we define electric potential (V):

$$V = \frac{U}{q} \quad (3.9)$$

Since $U \propto q$, then V is independent of q . And, we have

$$\Delta V = V_A - V_B = \frac{\Delta U}{q} \quad (3.10)$$

or

$$\Delta U = q\Delta V \quad (3.11)$$

The units for potential difference ΔV are Joules per Coulomb, which is referred to as a Volt¹. Whenever voltage is noted, it is understood to be the potential difference between two points.

Another fundamental constant is that over the electron volt (eV) which is the energy given to the fundamental charge accelerated through a potential difference of 1 volt.

$$1eV = (1.60 * 10^{-19}C)(1V) = (1.60 * 10^{-19}C)(1\frac{J}{C}) = 1.60 * 10^{-19}J \quad (3.12)$$

Due to conservation of energy

$$K + U = \text{constant} \quad (3.13)$$

where K is the Kinetic Energy and U is the Potential Energy

or

$$K_i + U_i = K_f + U_f \quad (3.14)$$

Example

Calculate the speed of an electron accelerated through 100V

$$K_i = 0, U_i = qV \quad (3.15)$$

$$K_f = \frac{1}{2}mv^2, U_f = 0 \quad (3.16)$$

Thus

$$qV = \frac{1}{2}mv^2 \quad (3.17)$$

¹The volt was named after Alessandro Volta

$$v = \sqrt{\frac{2qV}{m}} \quad (3.18)$$

$$v = \sqrt{\frac{2(-1.6 * 10^{-19}C)(-100 \frac{J}{C})}{9.11 * 10^{-31}kg}} \quad (3.19)$$

$$v = 5.93 * 10^6 \frac{m}{s} \quad (3.20)$$

Voltage and the Electric Field

Returning to the general formula for the potential energy of a point charge q at Point P relative to a reference Point R.

$$U_P = - \int_R^P \vec{F} \cdot d\vec{I} \quad (3.21)$$

given that $\vec{F} = q\vec{E}$:

$$U_P = -q \int_R^P \vec{E} \cdot d\vec{I} \quad (3.22)$$

as we defined $V = \frac{U}{q}$:

$$V_P = - \int_R^P \vec{E} \cdot d\vec{I} \quad (3.23)$$

From conservation of energy, the result is independent of the path chosen, so we can pick the path that is most convenient.

Special Case

Consider the special case with a positive charge at the origin. To calculate the potential at a point r relative to a potential of 0 at infinity. Let $P = r$, $R = \infty$, $d\vec{I} = d\vec{r} = \hat{r}dr$.

Using $\vec{E} = k\frac{q}{r^2}\hat{r}$:

$$V_r = - \int_{\infty}^r k\frac{q}{r^2}\hat{r} \cdot \hat{r} dr \quad (3.24)$$

$$V_r = - \int_{\infty}^r k\frac{q}{r^2} dr \quad (3.25)$$

$$V_r = k\frac{q}{r} \Big|_{\infty}^r = k\left(\frac{q}{r} - \frac{q}{\infty}\right) \quad (3.26)$$

$$V_r = k\frac{q}{r} \quad (3.27)$$

Let's calculate the potential difference between two points equidistant for the reference point.

Figure 3.5: Potential difference between two equidistant points

$$\Delta V_{AB} = V_B - V_A = - \int_A^B \vec{E} \cdot d\vec{I} \quad (3.28)$$

$$\Delta V_{AB} = - \int_A^B \frac{kq}{r^2} \hat{r} \cdot r \hat{\phi} d\phi \quad (3.29)$$

as $\hat{r} \cdot \hat{\phi} = 0$:

$$\Delta V_{AB} = 0 \quad (3.30)$$

Figure 3.6: Potential difference between two points

3.3 Calculations of Electric Potential

- From a Point Charge

$$V = \frac{kq}{r} \quad (3.31)$$

- From multiple Point Charges

$$V = k \sum_{i=1}^N \frac{q_i}{r_i} \quad (3.32)$$

- From a continuous charge

$$V = k \int \frac{dq}{r} \quad (3.33)$$

where

$$dq = \begin{cases} \lambda dl & (\text{in one dimension}) \\ \sigma dA & (\text{in two dimensions}) \\ \rho dV & (\text{in three dimensions}) \end{cases} \quad (3.34)$$

Potential due to a ring

Consider a disk with uniform charge density λ (Coulombs per meter arc length). Let's find the electric potential at a point on the axis passing through the center of the ring.

Figure 3.7: Ring of charge

The strategy is to divide the ring into infinitesimal elements shaped as arcs on the circle and to utility cylindrical coordinate system.

The element between angles θ and $\theta + d\theta$ is of length $Rd\theta$. It therefore contains charge $\lambda Rd\theta$. The element is at distance $\sqrt{z^2 + R^2}$ from point P. Therefore:

$$V_P = k \int \frac{dq}{r} = k \int_0^{2\pi} \frac{\lambda R d\theta}{\sqrt{z^2 + R^2}} = \frac{k\lambda R}{\sqrt{z^2 + R^2}} \int_0^{2\pi} d\theta \quad (3.35)$$

$$= \frac{k\lambda R}{\sqrt{z^2 + R^2}} \theta \Big|_0^{2\pi} = \frac{2\pi k\lambda R}{\sqrt{z^2 + R^2}} = k \frac{q_{tot}}{\sqrt{z^2 + R^2}} \quad (3.36)$$

Potential due to a disk

Consider a disk with uniform charge density σ (Coulombs per meter squared). Let's find the electric potential at a point on the axis passing through the center of the disk.

Figure 3.8: Disk of charge

The strategy is to divide the disk into ring-shaped elements, then taking the previous result integrate over r as well as θ .

The infinitesimal width ring elements between cylinder r and $r + dr$ will be a ring of charges whose electric potential dV_P at the field point is

$$dV_P = k \frac{dq}{\sqrt{z^2 + R^2}} \quad (3.37)$$

where

$$dq = \sigma 2\pi r dr \quad (3.38)$$

Integrating from $r = 0$ to $r = R$

$$V_P = \int dV_P = k2\pi\sigma \int_0^R \frac{r dr}{\sqrt{z^2 + r^2}} \quad (3.39)$$

$$= k2\pi\sigma \sqrt{z^2 + r^2} \Big|_0^R = k2\pi\sigma (\sqrt{z^2 + R^2} - \sqrt{z^2}) \quad (3.40)$$

3.4 Determining Field From Potential

Recall that

$$U = V_B - V_A = \int_A^B \vec{E} \cdot d\vec{s} \quad (3.41)$$

The electric field can be calculated by taking the derivative of U

For a uniform electric field

$$E = -\frac{\Delta V}{\Delta s} \quad (3.42)$$

where Δs is the distance over which the change in potential ΔV takes place.

For a continuously changing field, ΔV and Δs become infinitesimally small giving

$$E_s = -\frac{dV}{ds} \quad (3.43)$$

Calcworkshop.com

Figure 3.9: Partial Derivatives

Using Partial Derivatives, the electric field components in the Cartesian directions are given by

$$E_x = -\frac{\delta V}{\delta x}, E_y = -\frac{\delta V}{\delta y}, E_z = -\frac{\delta V}{\delta z} \quad (3.44)$$

Introducing the Gradient (grad) or Delta (del) vector operator:

$$\vec{\nabla} = \hat{i} \frac{\delta}{\delta x} + \hat{j} \frac{\delta}{\delta y} + \hat{k} \frac{\delta}{\delta z} \quad (3.45)$$

and thus

$$\vec{E} = -\vec{\nabla}V \quad (3.46)$$

For symmetric systems

- Cylindrical:

$$\vec{\nabla} = \hat{r} \frac{\delta}{\delta r} + \hat{\phi} \frac{1}{r} \frac{\delta}{\delta \phi} + \hat{z} \frac{\delta}{\delta z} \quad (3.47)$$

- Spherical:

$$\vec{\nabla} = \hat{r} \frac{\delta}{\delta r} + \hat{\theta} \frac{1}{r} \frac{\delta}{\delta \theta} + \hat{\phi} \frac{1}{r \sin \theta} \frac{\delta}{\delta \phi} \quad (3.48)$$

Example

Electric Field of a point charge

$$V = k \frac{q}{r} \text{ (spherically symmetric)} \quad (3.49)$$

$$\vec{E} = -\vec{\nabla}V \quad (3.50)$$

$$\vec{E} = -\left(\hat{r} \frac{\delta}{\delta r} + \hat{\theta} \frac{1}{r} \frac{\delta}{\delta \theta} + \hat{\phi} \frac{1}{r \sin \theta} \frac{\delta}{\delta \phi}\right) k \frac{q}{r} \quad (3.51)$$

$$\vec{E} = -kq \left(\hat{r} \frac{\delta}{\delta r} \left(\frac{1}{r} \right) + \hat{\theta} \frac{1}{r} \frac{\delta}{\delta \theta} \left(\frac{1}{r} \right) + \hat{\phi} \frac{1}{r \sin \theta} \frac{\delta}{\delta \phi} \left(\frac{1}{r} \right) \right) \quad (3.52)$$

$$\vec{E} = -kq \left(\hat{r} \left(\frac{-1}{r^2} \right) + \hat{\theta}(0) + \hat{\phi}(0) \right) \quad (3.53)$$

$$\vec{E} = +\frac{kq}{r^2}\hat{r} \quad (3.54)$$

Figure 3.10: Electric Field from Point Charge

Electric Field from Ring of Charge

Figure 3.11: Electric Field from Ring Of Charge

$$E_z = -\frac{\delta V}{\delta z} \text{ with } V = k\frac{kq_{tot}}{\sqrt{z^2 + R^2}} \quad (3.55)$$

$$E_z = -\frac{\delta}{\delta z}\left(k\frac{kq_{tot}}{\sqrt{z^2 + R^2}}\right) \quad (3.56)$$

Given that

$$\frac{\delta}{\delta z}\left(\frac{1}{\sqrt{z^2 + R^2}}\right) = \frac{\delta}{\delta z}(z^2 + R^2)^{-\frac{1}{2}} = -\frac{1}{2}(z^2 + R^2)^{-\frac{3}{2}}(2z) \quad (3.57)$$

We get

$$E_z = +k \frac{kq_{tot}z}{(z^2 + R^2)^{\frac{3}{2}}} \quad (3.58)$$

3.5 Electropotential Surfaces and Conductors

Figure 3.12: Red: Field Lines, Blue: Equipotential Lines

Equipotential Lines are always perpendicular to the electric field lines since along them $\Delta V = 0$.

$$W = -\Delta U = -q\Delta V = 0 \quad (3.59)$$

Work is zero when the direction of the force is perpendicular to displacement.

$$W = \vec{F} \cdot \vec{d} = q\vec{E} \cdot \vec{d} = qEd \cos \theta \text{ for } \theta = 90^\circ \text{ or } 270^\circ \quad (3.60)$$

Conductors

- One of the rules for static electric fields and conductors is that the \vec{E} is perpendicular (\perp) to the surface.
- This implies that a conductor is an equipotential surface in static situations. There can be no voltage difference across the surface of a conductor, or charges will flow.

- One of the uses of this fact is that a conductor can be fixed at what we consider zero volts by connecting it to the earth with a good conductor — a process called grounding.

Because a conductor is an equipotential, it can replace any equipotential surface. For example, a charged spherical conductor can replace the point charge, and the electric field and potential surfaces outside of it will be unchanged, confirming the contention that a spherical charge distribution is equivalent to a point charge at its center.

Figure 3.13: Potential lines, two opposite charges

Figure 3.14: Equipotential lines (as might be measured by a voltmeter) and corresponding electric field

One of the most important cases is that of the familiar parallel conducting plates. Between the plates, the equipotentials are evenly spaced and parallel. The same field could be maintained by placing conducting plates at the equipotential lines at the potentials shown.

Figure 3.15: Two parallel plates - \vec{E} and equipotential lines

Example - Calculating Equipotential Lines

Consider Figure 3.12 with $Q = +10nC$ at the Origin. What are the equipotential surfaces at which the potential is:

- (a) 100V
- (b) 50V
- (c) 20V
- (d) 10V

For $V = k\frac{q}{r}$, V is a constant. Thus, $r = k\frac{q}{V}$.

- (a) 100V: $r = k\frac{q}{V} = (8.99 * 10^9 \frac{Nm^2}{C^2}) \frac{10*10^{-9}C}{100V} = 0.90m$
- (b) 50V $r = 1.8m$
- (c) 20V $r = 4.5m$
- (d) 10V $r = 9.0m$

Example - Potential Difference between Oppositely Charged Parallel Plates

Figure 3.16: Oppositely charged parallel plates

Two large conducting plates carry equal and opposite charges, with a surface charge density $\sigma = 6.81 * 10^{-7} \frac{C}{m^2}$ of magnitude as shown in Figure 3.16. The separation between the plates is $l = 6.5mm$

- (a) What is the electric field between the plates?
- (b) What is the potential difference between the plates?
- (c) What is the distance between equipotential planes which differ by 100 V?

Assume the size of the plates (L) is much larger than the distance l .

$$\Delta V_{AB} = - \int_A^B \vec{E} \cdot d\vec{l} \quad (3.61)$$

- (a) Electric Field is directed from +plate to the -plate with magnitude

$$E = \frac{\sigma}{\epsilon_0} = \frac{6.81 * 10^{-7} \frac{C}{m^2}}{8.85 * 10^{-12} \frac{C^2}{Nm^2}} = 7.69 * 10^4 \frac{V}{m} \quad (3.62)$$

(b) The path from -plate to +plate is directed against \vec{E}

$$\vec{E} = d\vec{I} = -E \cdot dl \quad (3.63)$$

$$\Delta V = \int E \cdot dl = E \int dl = El = (7.69 * 10^4 \frac{V}{m})(6.5 * 10^{-3}m) = 500V \quad (3.64)$$

(c) Uniform electric field

$$\frac{500V}{6.5 * 10^{-3}m} = \frac{100V}{x} \quad (3.65)$$

$$x = 1.3 * 10^{-3}m \quad (3.66)$$

Distribution of Charges on Conductors

Figure 3.17: An isolated conducting sphere

$$\vec{E} = E(r)\hat{r} \quad (3.67)$$

Applying Gauss's Law over a closed surface s of radius r . As $r = \text{a constant}$, $\hat{r} = \hat{n}$ on the surface of the sphere.

$$\oint_s \vec{E} \cdot \hat{n} = E(r) \oint_s da = E(r)4\pi r^2 \quad (3.68)$$

For $r < R$: s is inside the conductor.

Magnitude

$$E(r) = \frac{1}{4\pi\epsilon_0} \frac{q_{enc}}{r^2} \quad (3.69)$$

$$q_{enc} = 0 \Rightarrow E(r) = 0 \quad (3.70)$$

For $r \geq R$: s encloses the conductor so $q_{enc} = q$

$$E(r) = \frac{1}{4\pi\epsilon_0} \frac{q}{r^2} \quad (3.71)$$

Electric Field

$$\vec{E} = \begin{cases} 0 & (r < R) \\ \frac{1}{4\pi\epsilon_0} \frac{q}{r^2} \hat{r} & (r \geq R) \end{cases} \quad (3.72)$$

Potential

- For $r < R$, $E = 0 \Rightarrow V(r)$ is constant, since $V(R) = \frac{1}{4\pi\epsilon_0} \frac{q}{R}$
- For $r \geq R$, potential is the same as a point charge: $V(R) = \frac{1}{4\pi\epsilon_0} \frac{q}{r}$

Figure 3.18: Two different radii

Now consider two conducting spheres of radii R_1 and R_2 connected by a thin conducting wire as shown in Figure 3.18

$$V = \frac{1}{4\pi\epsilon_0} \frac{q}{R} \quad (3.73)$$

Given that because of the conducting wire $V_1 = V_2$

$$\frac{1}{4\pi\epsilon_0} \frac{q_1}{R_1} = \frac{1}{4\pi\epsilon_0} \frac{q_2}{R_2} \quad (3.74)$$

$$\frac{q_1}{R_1} = \frac{q_2}{R_2} \quad (3.75)$$

Charge surface density σ :

$$q = \sigma(4\pi R^2) \quad (3.76)$$

Substituting in for q_1 and q_2 and simplifying

$$\sigma_1 R_1 = \sigma_2 R_2 \quad (3.77)$$

Different Radii of Curvature on the same object

Figure 3.19: Radius of Curvature

Different Radii of Curvature on the same object

- Large Radius of Curvature $\Rightarrow \sigma$ and E are small
- Point $\Rightarrow \sigma$ and E are extremely large

Lightning Rod

On a very sharply curved surface, such as shown in 3.20, the charges are so concentrated at the point that the resulting electric field can be great enough to remove them from the surface. This can be useful.

Lightning rods work best when they are most pointed. The large charges created in storm clouds induce an opposite charge on a building that can result in a lightning bolt hitting the building. The induced charge is bled away continually by a lightning rod, preventing the more dramatic lightning strike.

Figure 3.20: Lightning Rod

Chapter 4

Module 4 - Chapter 8 Capacitance

4.1 Capacitors and Capacitance

A capacitor is a device used to store electrical charge and electrical energy. Capacitors are generally with two electrical conductors separated by a distance. The space is usually filled with an insulating material known as a dielectric. The amount of storage in a capacitor is referred to as its capacitance.

Figure 4.1: Parallel Plate Capacitor

$$C = \frac{Q}{V} \tag{4.1}$$

Capacitance is measured in the Farad¹ (F). One farad is one coulomb per volt:
 $1F = \frac{1C}{1V}$.

Calculation of Capacitance

1. Assume that the capacitor has charge Q
2. Determine the electric field \vec{E}
3. Find the potential between the conductors from

$$V_B - V_A = - \int_A^B \vec{E} \cdot d\vec{l} \quad (4.2)$$

which leads to magnitude of the potential difference being $V = |V_B - V_A|$.

4. Find C from Equation 4.1

Parallel Plate Capacitor

Consider a parallel plate capacitor with each plate of area A separated by distance d . Assume when voltage V is applied, it stores charge Q .

Define the surface charge density σ as

$$\sigma = \frac{Q}{A} \quad (4.3)$$

When d is small compared to the size of the plates, the electric field between the plates is fairly uniform, with a magnitude give by:

$$E = \frac{\sigma}{\epsilon_0} \quad (4.4)$$

Since the electric field \vec{E} between the plates is uniform

$$V = Ed = \frac{\sigma d}{\epsilon_0} = \frac{Qd}{\epsilon_0 A} \quad (4.5)$$

From Equation 4.1:

$$C = \frac{Q}{V} = \frac{Q}{\frac{Qd}{\epsilon_0 A}} = \epsilon_0 \frac{A}{d} \quad (4.6)$$

¹Named after Michael Faraday

Cylindrical Capacitor

Figure 4.2: Cylindrical Capacitor

Consider the cylindrical capacitor with the inner cylinder (either solid or shell) of outer radius r_1 and out cylinder of inner radius r_2 . Assume the length is l and the excess charges $+Q$ and $-Q$ are on the inner and outer cylinders, respectively.

Ignoring the edge effect, the electric field \vec{E} radiates out radially from the common axis of the two cylinders. Using the Gaussian Surface shown in Figure 4.2, yields

$$\oint_S \vec{E} \cdot \vec{n} dA = E(2\pi r l) = \frac{Q}{\epsilon_0} \quad (4.7)$$

Therefore, the field between the two cylinders is

$$\vec{E} = \frac{1}{2\pi\epsilon_0} \frac{Q}{r l} \hat{r} \quad (4.8)$$

Substituting into Equation 4.2:

$$V = \int_{R_1}^{R_2} \vec{E} \cdot d\vec{l} = \frac{Q}{2\pi\epsilon_0 l} \int_{R_1}^{R_2} \frac{1}{r} \hat{r} \cdot (\hat{r} dr) = \frac{Q}{2\pi\epsilon_0 l} \int_{R_1}^{R_2} \frac{dr}{r} \quad (4.9)$$

$$= \frac{Q}{2\pi\epsilon_0 l} \ln(r) \Big|_{R_1}^{R_2} = \frac{Q}{2\pi\epsilon_0 l} \ln\left(\frac{R_2}{R_1}\right) \quad (4.10)$$

Thus

$$C = \frac{Q}{V} = \frac{2\pi\epsilon_0 l}{\ln\left(\frac{R_2}{R_1}\right)} \quad (4.11)$$

This is sometimes expressed at capacitance per unit length

$$\frac{C}{l} = \frac{2\pi\epsilon_0}{\ln\left(\frac{R_2}{R_1}\right)} \quad (4.12)$$

4.2 Capacitors in Series and Parallel

Capacitors in Series

When a series of capacitors are hooked up to a direct current voltage source (e.g., a battery) each acquires an identical charge Q .

- The plate connected to the positive terminal acquires a charge Q . And, the plate connected to the negative terminal acquires a charge $-Q$.
- A charge is then induced on each of the other plates so that the sum of the charge on all plates or on any pair of plates is zero.
- However, the potential drop on one pair of plates ($V_1 = \frac{Q}{C_1}$) may be different from a the drop across another pair of plates ($V_2 = \frac{Q}{C_2}$)

Figure 4.3: Capacitors in Series

The potentials must sum to the potential of the battery:

$$V = V_1 + V_2 + V_3 \quad (4.13)$$

The potential V is measured across a equivalent capacity holding charge Q , which is said to have an equivalent capacitance C_{EQ} . Leading to:

$$\frac{Q}{C_{EQ}} = \frac{Q}{C_1} + \frac{Q}{C_2} + \frac{Q}{C_3} \quad (4.14)$$

Thus:

$$\frac{1}{C_{EQ}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} \quad (4.15)$$

Capacitors in Parallel

If, instead, the three capacitors are connected in parallel, they will have the same voltage across each pair of plates

$$V = V_1 = V_2 = V_3 \quad (4.16)$$

Figure 4.4: Capacitors in Parallel

The total charge stored across the plates Q is the equivalent of the sum of the charges on each plate

$$Q = Q_1 + Q_2 + Q_3 \quad (4.17)$$

Given that $Q = C * V$:

$$C_{EQ}V = C_1V + C_2V + C_3V \quad (4.18)$$

And, thus:

$$C_{EQ} = C_1 + C_2 + C_3 \quad (4.19)$$

Capacitors in Series and Parallel

Consider the below with $C_1 = 1.0pF$, $C_2 = 2.0pF$, $C_3 = 4.0pF$, and $C_4 = 5.0pF$. Assume the voltage potential across each circuit is $12.0V$:

Figure 4.5: Capacitors in Series and Parallel

Energy Stored in a Capacitor

The energy U_C stored in a capacitor is electrostatic potential energy and is therefore related to the charge Q and the voltage V . The charged capacity stores energy in the electric field between the two plates.

The space between the plates has a volume Ad , where A is the area of the plates, and d is the distance between them. The energy density u_E is simply the total energy divided by the volume

$$U_C = u_E(Ad) \quad (4.20)$$

We will learn later (when we complete Maxwell's equations) that the energy density of free-space occupied by an electric field E only depends on the magnitude of the field

$$u_E = \frac{1}{2}\epsilon_0 E^2 \quad (4.21)$$

Thus

$$U_C = \frac{1}{2}\epsilon_0 E^2 Ad = \frac{1}{2}\epsilon_0 \frac{V^2}{d^2} Ad = \frac{1}{2}V^2\epsilon_0 \frac{A}{d} = \frac{1}{2}V^2C \quad (4.22)$$

Because $C = \frac{Q}{V}$:

$$U_C = \frac{1}{2}V^2C = \frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}QV \quad (4.23)$$

This expression for a parallel plate capacitor is generally valid for all types of capacitors. Consider an uncharged capacitor. At the instance that it is connected to the battery, the potential difference is between the the plates is $V = q/C$.

Initially

$$q = 0 \quad (4.24)$$

Gradually charge builds up on the plates. And, after some time it reaches the value $Q = CV$.

To move an infinitesimal charge dQ from the negative plate to the positive plate (from lower to higher potential) the amount of work dW that must be done on dq is

$$dW = VdQ = \frac{q}{C}dq \quad (4.25)$$

The work becomes the energy stored in the capacitor

$$W = \int_0^{W(Q)} dW = \int_0^Q \frac{q}{C}dq = \frac{1}{2}\frac{Q^2}{C} \quad (4.26)$$

As the geometry has not be specified, this is applicable to any type of capacitor. The total work W needed to charge a capacitor is the electrical potential energy, thus

$$U_E = W = \frac{1}{2}\frac{Q^2}{C} \quad (4.27)$$

which matches Equation 4.23.

Capacitor with a Dielectric

An insulating material placed between the plates of a capacitor is know as a dielectric.

Figure 4.6: Adding a Dielectric to a Capacitor

Consider a capacitor of capacitance C_0 with air between the electrodes. When it is fully charged and then disconnected from the power source the potential between the plates is measured at V_0 . Now suppose a dielectric is placed between the two plates. The new voltage is measured to be

$$V = \frac{1}{\kappa} V_0 \quad (4.28)$$

where κ is called the Dielectric Constant and $\kappa > 1$.

As the charge on the plate has not changed, this implies:

$$C = \frac{Q_0}{V} = \frac{Q_0}{\kappa V_0} = \kappa \frac{Q_0}{V_0} = \kappa C_0 \quad (4.29)$$

This, in turn, changes the potential energy stored in the capacitor

$$U = \frac{1}{2} \frac{Q^2}{C} = \frac{1}{2} \frac{Q_0^2}{\kappa C_0} = \frac{1}{\kappa} U_0 \quad (4.30)$$

Molecular Model of a Dielectric

We can understand the effect of the dielectric on the capacitance by looking at the molecular level.

Figure 4.7: Polarized Atom

When an external electric field \vec{E}_0 is applied, the polar molecules align. The opposite charges in adjacent dipoles with the volume of the dielectric neutralize each other, so there is no net charge within the dielectric. However, at the edges of the dielectric that are perpendicular to the electric field, this is not the case. This creates an induced surface charge $+Q_i$ and $-Q_i$. These produce an additional electric field, the induced electric field, \vec{E}_i that opposes \vec{E}_0 .

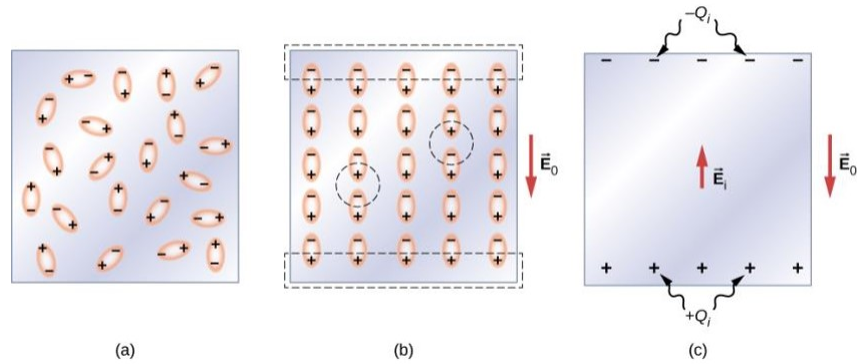

Figure 4.8: Dielectric Effect on Electric Field

Note: the same effect happens for non-polar molecules as they acquire an induced electric-dipole moment because of the external electric field.

The net electric field across the capacitor is

$$\vec{E} = \vec{E}_0 + \vec{E}_i \quad (4.31)$$

and the effective charge becomes

$$Q = Q_0 - Q_i \quad (4.32)$$

This leads to the definition of the dielectric constant (κ) as

$$\kappa = \frac{E_0}{E} \quad (4.33)$$

As E_i always opposes E_0 , E is always less than E_0 and $\kappa > 1$. All of this leads to

$$\vec{E}_i = \left(\frac{1}{\kappa} - 1\right)\vec{E}_0 \quad (4.34)$$

If the magnitude of the electric field becomes too large, the molecules in the dielectric become ionized creating free electrons and the material becomes conducting. This is known as dielectric breakdown.

The critical value of the electric field (E_C) at which molecules in an insulator become conducting is called the dielectric strength.

For air, $E_C = 3.0 \frac{MV}{m}$, so for an air-filled capacitor with a plate separation of $d = 1.00mm$:

$$V = E_C d = (3.0 * 10^6 \frac{V}{m})(1.0 * 10^{-3} m) = 3.0kV. \quad (4.35)$$

Chapter 5

Current and Resistance

Electric Current

Electric current is defined as the rate at which charge flows.

$$I = \frac{\Delta Q}{\Delta t} \quad (5.1)$$

where the unit for I is the ampere ¹ (A) where

$$1A = 1\frac{C}{s} \quad (5.2)$$

Instantaneous electric current

$$I = \lim_{\Delta t \rightarrow 0} \frac{\Delta Q}{\Delta t} = \frac{dQ}{dt} \quad (5.3)$$

Figure 5.1: Rate of Flow

¹named for French physicist Andr -Marie Amp re

Example: Calculating Instantaneous Current

Consider a charge moving in a cross-section of wire where the charge is modeled as

$$Q(t) = Q_M(1 - e^{-\frac{t}{\tau}}) \quad (5.4)$$

where Q_M is the charge after a long time ($t \rightarrow \infty$)).

Figure 5.2: Charge moving through a wire over time

Using the equality:

$$\frac{d}{dx}e^u = e^u \frac{du}{dx} \quad (5.5)$$

$$I = \frac{dQ}{dt} = \frac{d}{dt}[Q_M(1 - e^{-\frac{t}{\tau}})] = \frac{Q_M}{\tau}e^{-\frac{t}{\tau}} \quad (5.6)$$

Figure 5.3: Current through a wire over time

Current in a Circuit

When the switch is closed, current flows

Figure 5.4: Current in a circuit

Conventionally, the direction of current represents the direction that positive charge would flow (positive terminal to negative terminal). However, we know that in fact, it is electrons (negative charge) that is flowing in the wire in the opposite direction of the current.

Figure 5.5: Direction of flow

5.1 Model of Conduction in Metals

Drift Velocity

The electrical signals carried by currents travel at a significant portion of the speed of light (of the magnitude of 10^8 m/s. However, individual electrons typically drift at speeds are around 10^{-4} m/s. How are these two different speeds reconciled?

The high speed electrical signals result from the force between charges acting rapidly at a distance. When free charge is forced into a wire, the incoming charge pushes on the other charges ahead of it due to the repulsive force between like charges. The density of charge in the wire can't be readily increased, so the signal is passed rapidly. The resulting electrical "shock wave" moves through the system near the speed of light. To be precise, the fast-moving signal is a rapidly propagating change in the electric field.

Figure 5.6: Charge in a volume

However, as the individual free charges (electrons) move, they collide with atoms in the conductor. The distance the electrons move before collision is quite small. The electron paths appear to be random; however, there is an electric field in the conductor that causes the electrons to drift in the direction opposite the field. The drift velocity \vec{V}_d is the average velocity of the free charges.

Figure 5.7: Drift

The relationship between current and drift velocity can be found by considering the number of free charges in a segment of wire. The number density of free charges (n) is given by

$$n = \frac{\text{number of charges}}{\text{volume}} \quad (5.7)$$

where the value of n depends on the material.

Figure 5.8: Drift Velocity

Consider the volume $Av_d dt$. The number of charges is thus $nAv_d dt$, and therefore $dQ = qnAv_d dt$.

From the current definition:

$$I = \frac{dQ}{dt} = qnAv_d \quad (5.8)$$

This leads to a drift velocity of

$$v_d = \frac{I}{nqA} \quad (5.9)$$

Current Density

While current is a scalar with a $+$ or $-$ to indicate direction, it is sometimes useful to consider the details of the motion of the charge.

We will consider the current density, \vec{J} , the flow of charge through an infinitesimal area, divided by the area. Consider the differential current through an area of \vec{A}

$$dI = \vec{J} \cdot d\vec{A} = JdA \cos \theta \quad (5.10)$$

Integrating

$$I = \iint_{area} \vec{J} \cdot d\vec{A} \quad (5.11)$$

Consider the magnitude of the current density

$$J = \frac{I}{A} = \frac{n|q|Av_d}{A} = n|q|v_d \quad (5.12)$$

Thus

$$\vec{J} = nq\vec{v}_d \quad (5.13)$$

Resistivity and Resistance

When a voltage is applied to a conductor an electric field \vec{E} is created and charges in the conductor experience the force from the electric field. The resulting current density, \vec{J} , depends on the electric field and properties of the conductor:

$$\vec{J} = \sigma \vec{E} \quad (5.14)$$

where σ is the electrical conductivity of the material.

$$\sigma = \frac{|J|}{|E|} \left(\frac{A}{V \cdot m} \right) \quad (5.15)$$

Next we define the ohm² (Ω). The Ω is defined at $\frac{1V}{1A}$, given σ the units of $(\Omega \cdot m)^{-1}$.

The inverse of conductivity is resistivity (ρ):

$$\rho = \frac{1}{\sigma} (\Omega \cdot m) \quad (5.16)$$

We can define resistivity in terms of Electric Field and Current Density

$$\rho = \frac{E}{J} \quad (5.17)$$

Example - Copper Wire

Consider 5 meters of copper wire of diameter $2.053mm$ (12-gauge) carrying a current of $10mA$.

²Names for Georg Simon Ohm

First calculate the current density

$$J = \frac{I}{A} = \frac{10 * 10^{-3}}{(2.053 * 10^{-3})^2 \pi} \frac{A}{m^2} = \frac{10 * 10^{-3}}{3.31 * 10^{-6}} \frac{A}{m^2} = 3.0 * 10^3 \frac{A}{m^2} \quad (5.18)$$

Next, the resistance use $\rho_{copper} = 1.68 * 10^{-8}(\Omega \cdot m)$:

$$R = \rho \frac{L}{A} = 1.68 * 10^{-8}(\Omega \cdot m) \frac{5.00m}{3.31 * 10^{-6}m^2} = 0.025\Omega \quad (5.19)$$

Finally, the Electric Field

$$E = \rho J = 1.68 * 10^{-8}(\Omega \cdot m) \cdot 3.0 * 10^3 \frac{A}{m^2} = 5.07 * 10^{-5} \frac{V}{m} \quad (5.20)$$

This hints at Ohm's Law $A \cdot \Omega = V$ or $V = IR$.

Temperature Dependence of Resistivity

The Resistivity Table contains "Temperature Coefficient" as some materials the resistivity has a strong temperature dependence.

$$\rho = \rho_0[1 + \alpha(T - T_0)] \quad (5.21)$$

where ρ_0 at T_0 are the resistivity at room temperature (usually assumed to be $20^\circ C$).

Resistance

Resistance is a measure of how difficult it is for current to pass through a wire.

Consider this diagram:

Figure 5.9: Resistance

$$E = \rho J \quad (5.22)$$

$$\frac{V}{L} = \rho \frac{I}{A} \quad (5.23)$$

$$V = \left(\rho \frac{L}{A}\right) I \quad (5.24)$$

This leads us closer to Ohm's Law. The Resistance is defined as the ratio of Voltage to Current or

$$R = \frac{V}{I} \quad (5.25)$$

Application

Combining the concept of Resistance with Temperature Dependence, we get

$$R = R_0(1 + \alpha \Delta T) \quad (5.26)$$

where ΔT is the difference in temperature relative to room temperature.

This is how a digital thermometer works.

5.2 Ohm's Law

The relationship between Voltage and Current was empirically determined by Goerg Ohm³

Figure 5.10: Goerg Ohm's Setup

Figure 5.11: Goerg Ohm's Data

Ohm's Law

$$V = I \cdot R \quad (5.27)$$

Diode

A diode allows current to flow in one direction. It has low resistance when forward biased and high resistance when reverse biased. Until breakdown.

³A presented in a paper published in 1827

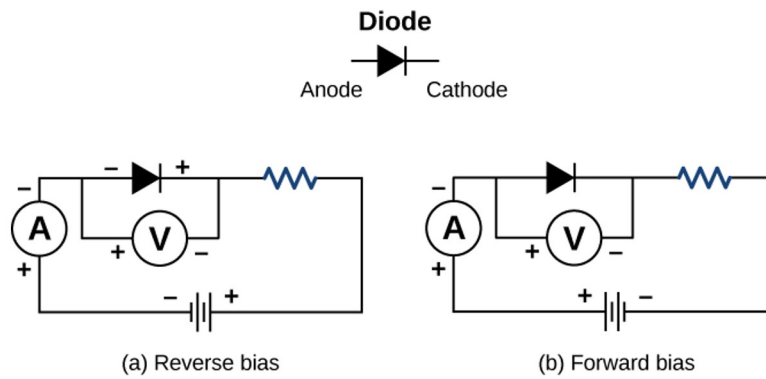

Figure 5.12: Diode Setup

Figure 5.13: Diode Resistance

5.3 Electrical Energy and Power

Figure 5.14: Power

To explore electric power, consider a voltage difference existing across a material. An electric potential difference exists with V_1 being higher than V_2 which is caused

by an Electric field pointing from the higher to lower potential. Recall that $V = \frac{\Delta U}{q}$ and that a charge ΔQ loses potential energy moving through the potential difference.

$$\vec{F} = m\vec{a} = \Delta Q \vec{E} \quad (5.28)$$

The force does not accelerate the charge across the entire length ΔL as the charge interacts with the atoms and free electrons in the material. Thus, the charge has the same Drift Velocity v_d passing through A_2 as it does at A_1 . However, there is work done on the charge.

$$E = \frac{(V_2 - V_1)}{\Delta L} = \frac{V}{\Delta L} \quad (5.29)$$

$$W = F\Delta L = (\Delta QE)\Delta L = (\Delta Q \frac{V}{\Delta L})\Delta L = \Delta QV = \Delta U \quad (5.30)$$

The lost potential energy appears as thermal energy in the material.

Power is work per unit time.

$$P = \frac{\Delta U}{\Delta t} = \frac{\Delta QV}{\Delta t} = IV \quad (5.31)$$

For a resistor

$$P = IV = I(IR) = I^2R \quad (5.32)$$

or

$$P = IV = \frac{V}{R} = \frac{V^2}{R} \quad (5.33)$$

The units for power is Watts (W):

$$1W = (1A)(1V) = (1\frac{C}{s})(1\frac{J}{C}) = 1\frac{J}{s} \quad (5.34)$$

Cost of Electricity

You pay for energy used. Power is change in Energy over time or $P = \frac{dE}{dt}$. This leads to

$$E = \int P dt \quad (5.35)$$

Cost Effectiveness of an LED Bulb

Consider that a 7.5W LED bulb has the same light output as a 100W incandescent bulb.

$$E_{incan} = Pt = 75W \left(\frac{1kW}{1000W} \right) \left(\frac{3h}{day} \right) 365days = 81.125kW \cdot h \quad (5.36)$$

$$E_{LED} = Pt = 7.5W \left(\frac{1kW}{1000W} \right) \left(\frac{3h}{day} \right) 365days = 8.113kW \cdot h \quad (5.37)$$

The average cost of electricity in Albuquerque is $14.60 \frac{cents}{kWh}$

$$\Delta Cost = (81.125kWh - 8,113kWh) * \frac{\$0.146}{kWh} = \$10.66 \quad (5.38)$$

5.4 Superconductors

Figure 5.15: Superconductor

In 1911, Heike Kamerlingh Onnes found that when mercury was cooled below a critical temperature ($4.2^\circ K$) the resistance went to zero. Zero resistance means no power loss as $P = I^2 R$

Additionally, there is a second effect, the exclusion of magnetic fields. Known as the Meissner effect allowing a light magnet to levitate above a superconducting surface.

Chapter 6

Direct Current Circuits

6.1 Electromotive Force

A special type of potential difference is the Electromotive Force (EMF). It is not a force, but it is still called this for historical¹ reasons.

Where does EMF come from. A battery can be considered a two-terminal device with one terminal always at a higher potential than the other. The higher terminal is referred to as the positive terminal (+) and the low potential terminal referred to as the negative terminal (-).

Figure 6.1: Electromotive Force

To maintain the higher potential on the positive terminal, negative charges must be moved to the negative terminal. This requires work which is supplied by the chemical reaction and this is what is referred to as the EMF. The EMF is equal to

¹Alessandro Volta coined the term EMF in the 1800s

the work done on the charge per unit charge:

$$\epsilon = \frac{dW}{dq} \quad (6.1)$$

when there is no charge flowing. Since the unit for work is the Joule and the unit for charge is the Coulomb, the unit for EMF is the volt ($1V = \frac{J}{C}$).

Internal Resistance and the Terminal Voltage

Batteries have internal resistance, so

$$V_{terminal} = \epsilon - Ir \quad (6.2)$$

Figure 6.2: Voltage Source and Load

Figure 6.3: Voltage through the circuit

6.2 Resistors in Series and Parallel

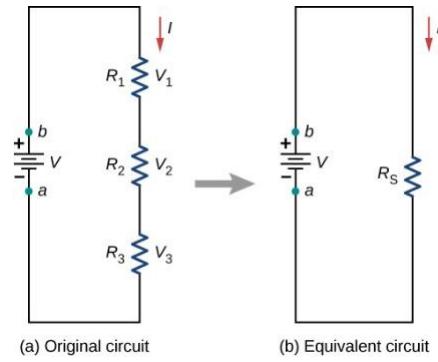

Figure 6.4: Resistors in Series

For resistors in Series

$$V = V_1 + V_2 + V_3 \quad (6.3)$$

$$V = 1R_1 + 1R_2 + 1R_3 \quad (6.4)$$

$$I = \frac{V}{R_1 + R_2 + R_3} \quad (6.5)$$

So

$$R_{eq} = \sum_{i=1}^N R_i \quad (6.6)$$

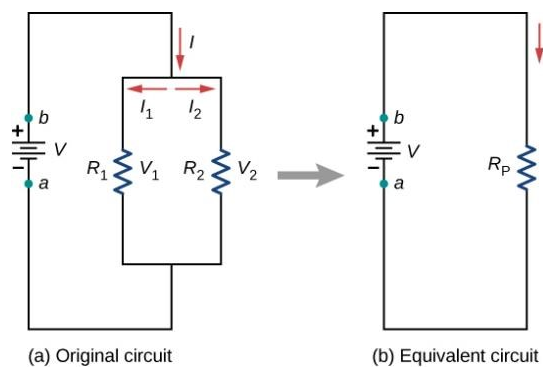

Figure 6.5: Resistors Parallel

$$V = V_1 = V_2 \quad (6.7)$$

$$I = I_1 + I_2 \quad (6.8)$$

$$\frac{V}{R_{eq}} = \frac{V_1}{R_1} + \frac{V_2}{R_2} \quad (6.9)$$

Because the Voltage is equal across the resistors

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} \quad (6.10)$$

Or, more generically

$$R_{eq} = \left(\sum_{i=1}^N \frac{1}{R_i} \right)^{-1} \quad (6.11)$$

Figure 6.6: Resistors in Series and Parallel

6.3 Kirchhoff's Laws

Kirchhoff's First Law (the Node Law or the Junction Rule)

The sum of all currents entering a junction must equal the sum of all currents leaving the junction.

$$\sum I_{\text{in}} = \sum I_{\text{out}}$$

$$I_1 + I_2 + I_4 + I_5 = I_3 + I_6$$

Figure 6.7: Kirchhoff's Node Law

$$\sum I_{\text{in}} = \sum I_{\text{out}} \quad (6.12)$$

Figure 6.8: Kirchhoff's Node Law Example

Kirchhoff's Second Law (the Loop Law or the Loop Rule)

The sum of all potential differences, including those supplied by voltage sources and resistive elements, around a closed loop equals zero.

Figure 6.9: Kirchhoff's Loop Law

$$\sum_{\text{closed loop}} V = 0 \quad (6.13)$$

Figure 6.10: Kirchhoff's Loop Law Example

Kirchhoff Examples

Figure 6.11: Kirchhoff Example

Figure 6.12: Kirchhoff Examples

6.4 RC Circuits

Figure 6.13: RC Circuit

When the switch is moved to Position A, from Kirchhoff's Loop Law

$$\epsilon - V_R - V_C = 0 \quad (6.14)$$

The voltage across C is $V_C = \frac{q}{C}$ and the voltage across R is $V_R = IR$ with the current $I = \frac{dq}{dt}$.

$$\epsilon - R \frac{dq}{dt} - \frac{q}{C} = 0 \quad (6.15)$$

This differential equation can be solved by rearranging

$$\frac{dq}{dt} = \frac{\epsilon C - q}{RC} \quad (6.16)$$

$$\int_0^q \frac{dq}{\epsilon C - q} = \frac{1}{RC} \int_0^t dt \quad (6.17)$$

By substitution if $u = \epsilon C - q$ then $du = -dq$

$$- \int_0^q \frac{du}{u} = \frac{1}{RC} \int_0^t dt \quad (6.18)$$

Integrating

$$\ln \frac{\epsilon C - q}{\epsilon C} = -\frac{1}{RC} t \quad (6.19)$$

$$\frac{\epsilon C - q}{\epsilon C} = e^{-\frac{t}{RC}} \quad (6.20)$$

Simplifying

$$q(t) = C\epsilon(1 - e^{-\frac{t}{RC}}) = Q(1 - e^{-\frac{t}{\tau}}) \quad (6.21)$$

Where τ is the RC Time Constant ($\tau = RC$).

Note, as time approaches ∞ , the exponential goes to zero, so the charge approaches the maximum charge $Q = C\epsilon$.

The current can likewise be calculated

$$I(t) = \frac{dq}{dt} = \frac{d}{dt}[C\epsilon(1 - e^{-\frac{t}{RC}})] \quad (6.22)$$

$$I(t) = C\epsilon(\frac{1}{RC})e^{-\frac{t}{RC}} = \frac{\epsilon}{R}e^{-\frac{t}{RC}} = I_0e^{-\frac{t}{\tau}} \quad (6.23)$$

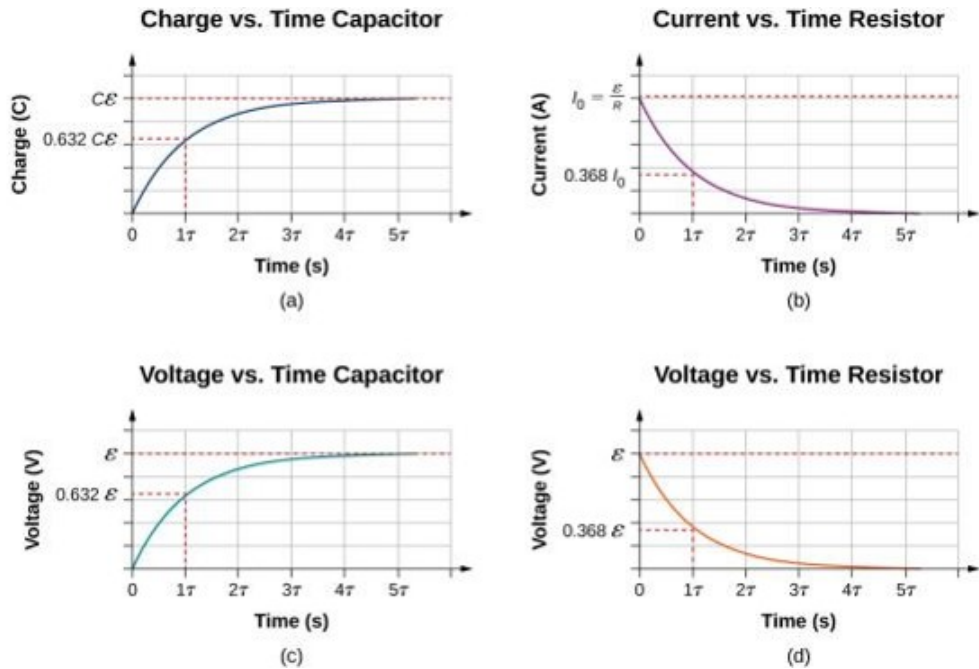

Figure 6.14: RC Circuit Charging

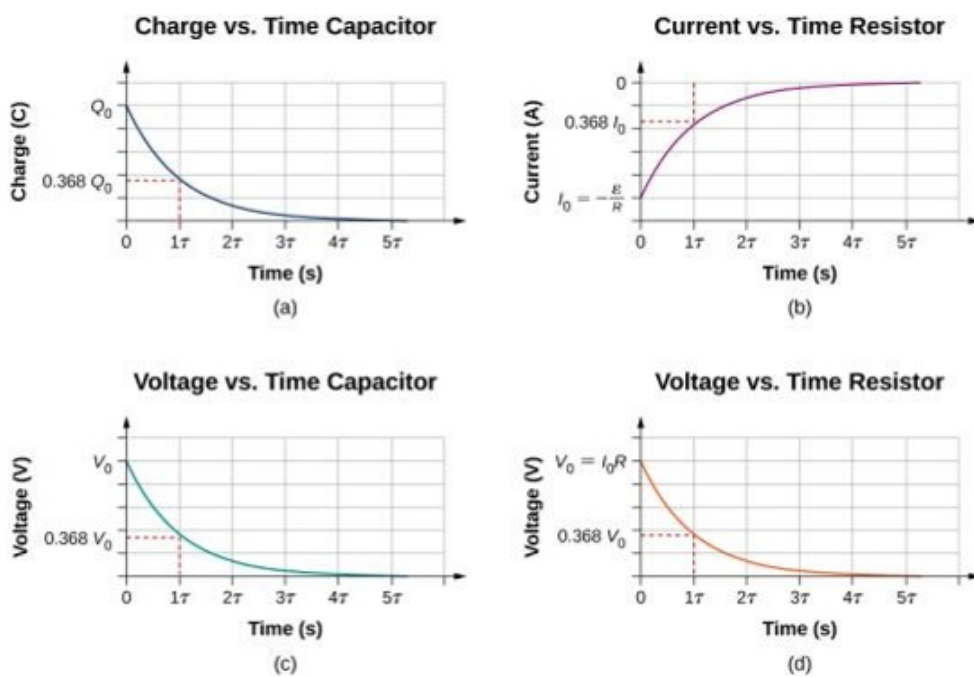

Figure 6.15: RC Circuit Discharging

Chapter 7

Magnetic Forces and Fields

We all know one big magnet. The North of the compass points towards the South pole of the magnet. So, the Geographic North Pole is actually near the Magnetic South Pole.

Figure 7.1: One Big Magnet

7.1 Magnetic Fields and Lines

A magnetic field is defined by the force of that a charged particle experiences moving in this field. The magnitude of the force is proportional to the amount of charge q , the speed of the charged particle v , and the magnitude of the applied magnetic field. The direction is perpendicular to both the direction of the moving charged particle and the direction of the applied magnetic field.

$$\vec{F}_m = q\vec{v} \times \vec{B} \quad (7.1)$$

where θ is the angle between the velocity and the magnetic field and the \vec{B} is defined as the magnetic field.

This gives a magnitude of

$$F_m = qvB\sin\theta \quad (7.2)$$

where the units for B are tesla (T).

$$1T = \frac{1N}{A \cdot m} \quad (7.3)$$

Sometimes it is useful to use a smaller unit, the gauss (G), where $1G = 10^{-4}T$.

The direction of the Magnetic Force is given by the right hand rule:

Figure 7.2: Right Hand Rule

Example

Figure 7.3: Magnetic Force on Alpha-Particle

Consider an alpha-particle ($q = 3.2 \times 10^{-19}C$) moving through a uniform magnetic field of magnitude $1.5T$. The direction of the field is parallel to the positive z -axis. What is the magnetic force on the alpha-particle when it is moving:

- (a) $5.0 \times 10^4 \frac{m}{s}$ in the positive x -direction

$$\vec{F} = q\vec{v} \times \vec{B} \quad (7.4)$$

$$\vec{F} = (3.2 \times 10^{-19}C)(5.0 \times 10^4 \frac{m}{s} \hat{i}) \times (1.5T \hat{k}) = -2.4 \times 10^{-14}N \hat{j} \quad (7.5)$$

- (b) $5.0 \times 10^4 \frac{m}{s}$ in the negative y -direction

$$\vec{F} = (3.2 \times 10^{-19}C)(-5.0 \times 10^4 \frac{m}{s} \hat{j}) \times (1.5T \hat{k}) = -2.4 \times 10^{-14}N \hat{i} \quad (7.6)$$

- (c) $5.0 \times 10^4 \frac{m}{s}$ in the positive z -direction

$$\vec{F} = (3.2 \times 10^{-19}C)(5.0 \times 10^4 \frac{m}{s} \hat{k}) \times (1.5T \hat{k}) = 0 \quad (7.7)$$

(d) with a velocity of $\vec{v} = (2.0\hat{i} - 3.0\hat{j} + 1.0\hat{k}) * 10^4 \frac{m}{s}$

$$\vec{F} = (3.2 * 10^{-19}C)((2.0\hat{i} - 3.0\hat{j} + 1.0\hat{k}) * 10^4 \frac{m}{s}) \times (1.5T\hat{k}) \quad (7.8)$$

Solving, rearranging to the order we are use to $(\hat{i} + \hat{j} + \hat{k})$:

$$\vec{F} = (-14.4\hat{i} - 9.6\hat{j}) * 10^{-15}N \quad (7.9)$$

This can also be represented as a magnitude and angle:

$$|\vec{F}| = \sqrt{((-14.4)^2 + (-9.6)^2)} * 10^{-15}N = 1.7 * 10^{-14}N \quad (7.10)$$

and

$$\theta = \arctan \frac{-9.6 * 10^{-15}N}{-14.4 * 10^{-15}N} = 34^\circ \quad (7.11)$$

Representing Magnetic Fields

- The direction of the magnetic field is tangent to the field line at any point in space.
- The strength of the field is proportional to the closeness of the lines.
- Magnetic field lines can never cross
- Magnetic field lines are continuous, forming closed loops without a beginning or end. They are directed from the North Pole to the South Pole.

The last property is related to the fact hat North and South poles can not be separated. This makes then different from electric field lines.

Figure 7.4: Magnetic Field Lines

7.2 Motion of Charged Particle In a Magnetic Field

Consider the case where the charged particle moves perpendicular to a uniform B-field.

Figure 7.5: Motion in a Magnetic Field

The magnetic force supplies the centripetal force $F_c = \frac{mv^2}{r}$. Noting the velocity is perpendicular to the magnetic field, the magnetic force reduces to $F_m = qvB$. Because F_m supplies F_c :

$$qvB = \frac{mv^2}{r} \quad (7.12)$$

Solving for r yields:

$$r = \frac{mv}{qB} \quad (7.13)$$

The period can then be derived as

$$T = \frac{2\pi r}{v} = \frac{2\pi}{v} \frac{mv}{qB} = \frac{2\pi m}{qB} \quad (7.14)$$

If the velocity is not perpendicular to the magnetic field then the velocity can be broken into components

$$v_{\text{perp}} = v \sin \theta \quad (7.15)$$

and

$$v_{\text{para}} = v \cos \theta \quad (7.16)$$

The parallel motion determines the pitch (p) of the helix

$$p = v_{\text{para}} T \quad (7.17)$$

Figure 7.6: Helical Motion

7.3 Magnetic Force on a Current-Carrying Conductor

A moving charge experiences a force in a magnetic field. If the charges are moving in a wire, then the wire will also experience the force. Before we explore this, let's consider how a magnetic field is generated by an electric current.

Magnetic Fields Produced By Electrical Currents

In 1820, a Danish physicist, Hans Christian Oersted, discovered that there was a relationship between electricity and magnetism. By setting up a compass through a wire carrying an electric current, Oersted showed that moving electrons can create a magnetic field.

The compass needle near a wire experiences a force that aligns the needle tangent to a circle around the wire. Therefore, a current carrying wire produces circular loops of magnetic field. This leads us to the second right hand rule

Figure 7.7: Right Hand Rule Revisited

Calculating the Magnetic Force

Recall that the current in a wire is given by

$$I = nqAv_d \quad (7.18)$$

where n is charge particle density, q is the charge, A is the cross sectional area of the wire, and v_d is the drift velocity.

Consider the magnetic force of a single charge: $q\vec{v} \times \vec{B}$. The magnetic force $d\vec{F}$ on the $nA \cdot dl$ segment of the wire is

$$d\vec{F} = (nA \cdot dl)q\vec{v}_d \times \vec{B} \quad (7.19)$$

We can define \vec{dl} to be a vector of length dl pointing along \vec{V}_d :

$$d\vec{F} = nqAv_d\vec{dl} \times \vec{B} \quad (7.20)$$

which leads to

$$d\vec{F} = I\vec{dl} \times \vec{B} \quad (7.21)$$

Integrating

$$\vec{F} = I\vec{l} \times \vec{B} \quad (7.22)$$

Example - Force on a Circular Wire

Consider a circular loop of radius carrying a current I that is placed on the xy plane. A constant uniform magnetic field cuts through the loop parallel to the y -axis. Find the magnetic force on the upper half, lower half, and the total force on the loop.

Figure 7.8: Magnetic Force on a Loop

The differential force on an arbitrary piece of wire located in the upper ring is

$$dF = IB \sin \theta dl \quad (7.23)$$

where θ is the angle between the magnetic field and the segment of wire. As $dl = R d\theta$:

$$dF = IBR \sin \theta d\theta \quad (7.24)$$

Integrating over the top half of the circle

$$F = IRB \int_0^\pi \sin \theta d\theta = IBR \Big|_0^\pi = 2IBR \quad (7.25)$$

Similarly, for the lower loop

$$F = IRB \int_\pi^{2\pi} \sin \theta d\theta = IBR \Big|_\pi^{2\pi} = -2IBR \quad (7.26)$$

And the total force is thus equal to zero.

Appendix A

Integration by Trig Substitution

Find the integral of

$$\int \frac{1}{(a^2 + x^2)^{\frac{3}{2}}} \quad (\text{A.1})$$

Integrate by trig substitution by setting $x = a \tan u$ which leads to

$$\frac{dx}{du} = \frac{a \tan u}{du} = \frac{a}{\cos^2 u} \quad (\text{A.2})$$

Which leads to

$$dx = \left(\frac{a}{\cos^2 u}\right) du \quad (\text{A.3})$$

Thus

$$\int \frac{1}{(a^2 + x^2)^{\frac{3}{2}}} = \int \frac{1}{(a^2 + (a \tan(u))^2)^{\frac{3}{2}}} \left(\frac{a}{\cos^2(u)}\right) du \quad (\text{A.4})$$

$$= \int \frac{1}{(a^2)^{\frac{3}{2}} (1 + \tan^2(u))^{\frac{3}{2}}} \left(\frac{a}{\cos^2(u)}\right) du \quad (\text{A.5})$$

$$= \int \frac{1}{(a^3) \left(\frac{1}{\cos^2(u)}\right)^{\frac{3}{2}}} \left(\frac{a}{\cos^2(u)}\right) du \quad (\text{A.6})$$

$$= \frac{1}{a^2} \int \frac{1}{\left(\frac{1}{\cos^2(u)}\right)^{\frac{3}{2}}} \left(\frac{1}{\cos^2(u)}\right) du \quad (\text{A.7})$$

$$= \frac{1}{a^2} \int \frac{1}{\left(\frac{1}{\cos^3(u)}\right)} \left(\frac{1}{\cos^2(u)}\right) du \quad (\text{A.8})$$

$$= \frac{1}{a^2} \int \cos(u) du \quad (\text{A.9})$$

$$= \frac{1}{a^2} \sin(u) + C \quad (\text{A.10})$$

From the above $\arctan\left(\frac{x}{a}\right) = u$ so

$$= \frac{1}{a^2} \sin\left(\arctan\left(\frac{x}{a}\right)\right) + C \quad (\text{A.11})$$

$$= \frac{1}{a^2} \left[\frac{\frac{x}{a}}{\sqrt{1 + \left(\frac{x}{a}\right)^2}} \right] + C \quad (\text{A.12})$$

$$= \frac{x}{a^3} \left[\frac{1}{\frac{1}{a} \sqrt{a^2 + x^2}} \right] + C \quad (\text{A.13})$$

Which finally leads to

$$\int \frac{1}{(a^2 + x^2)^{\frac{3}{2}}} = \frac{x}{a^2} \left[\frac{1}{\sqrt{a^2 + x^2}} \right] + C \quad (\text{A.14})$$

Appendix B

Chain Rule

$$\frac{d}{dx}\left(\frac{1}{\sqrt{x^2 + R^2}}\right) = \frac{d}{dx}(x^2 + R^2)^{-\frac{1}{2}} \quad (\text{B.1})$$

The chain rule $f(g(x))' = f'(g(x)) \cdot g'(x)$. In this case $g(x) = x^2 + R^2$. From this

$$f(g(x)) = g(x)^{-\frac{1}{2}} \quad (\text{B.2})$$

thus

$$f'(g(x)) = -\frac{1}{2}g(x)^{-\frac{3}{2}} \quad (\text{B.3})$$

and

$$g'(x) = 2x \quad (\text{B.4})$$

Thus

$$f(g(x))' = -\frac{1}{2}g(x)^{-\frac{3}{2}} \cdot 2x \quad (\text{B.5})$$

$$\frac{d}{dx}\left(\frac{1}{\sqrt{x^2 + R^2}}\right) = \frac{-x}{(x^2 + R^2)^{\frac{3}{2}}} \quad (\text{B.6})$$
